## ABSTRACT

**Key words:** keyword1 – keyword2 – keyword3

## 1 INTRODUCTION

## 2 METHODS

Starry from becky's paper [Smethurst et al. \(2015\)](#). Becky's group environment paper [Smethurst et al. \(2017\)](#). UltraVista catalogue paper [Muzzin et al. \(2013\)](#)

## 3 DATA

### 3.1 Multi-wavelength data

In this study we used the  $K_s$ -selected catalog of the COSMOS/UltraVISTA field from [Muzzin et al. \(2013\)](#). The catalog contains PSF-matched photometry in 30 photometric bands covering the wavelength range  $0.15\mu\text{m} \rightarrow 24\mu\text{m}$  and includes the available *GALEX* ([Martin et al. 2005](#)), CFHT/Subaru ([Capak et al. 2007](#)), UltraVISTA ([McCracken et al. 2012](#)), S-COSMOS ([Sanders et al. 2007](#)), and zCOSMOS ([Lilly et al. 2009](#)) datasets.

- Used rest frame U-V and V-J colours provided by [Muzzin et al. \(2013\)](#)
- These were calculated using the EAZY code [Brammer et al. \(2008\)](#), and the errors obtained from the error template in this paper.
- Filters for the bands: U,V Johnson filters from [Maíz Apellániz \(2006\)](#), J - 2Mass Filter from [Skrutskie et al. \(2006\)](#).

We required the rest-frame U - V and V - J colours found in [Muzzin et al. \(2013\)](#), which were calculated using the EAZY code ([Brammer et al. 2008](#)). For the U and V filters the Johnson response curves calculated in [Maíz Apellániz \(2006\)](#) were used. The J filter used the 2MASS response curve from [Skrutskie et al. \(2006\)](#).

Used rest frame U-V and V-J colours provided by [Muzzin et al. \(2013\)](#) These were calculated using the EAZY code [Brammer et al. \(2008\)](#), and the errors obtained from

the error template in this paper. Filters for the bands: U,V Johnson filters from [Maíz Apellániz \(2006\)](#), J - 2Mass Filter from [Skrutskie et al. \(2006\)](#).

### 3.2 Environment data

Environment data was obtained from [Darvish et al. \(2015\)](#). The method used to estimate environment was weighted Voronoi Tessellation (WVT) which is an iteration on the simple Voronoi Tessellation technique ([Ebeling & Wiedemann 1993](#); [Bernardeau & van de Weygaert 1996](#)). In simple Voronoi Tessellation, galaxies are divided into redshift planes in order to estimate local density. WVT uses a Monte-Carlo acceptance-rejection process to incorporate a weighted contribution from each galaxy in the density estimate. The weight assigned to each galaxy corresponds to the likelihood of it residing in the particular redshift slice being examined. Weighting the contributions aims to reduce the impact of redshift uncertainties on the density estimates.

[Darvish et al. \(2015\)](#) showed that WVT outperforms several other density estimation methods when evaluated against known surface density profiles. Moreover, unlike other density estimators (nearest neighbor methods) WVT makes no underlying assumptions about the geometry and morphology of the structures in the density field. (However it is noted that Voronoi Tessellation can not be used to assign density estimates to galaxies near the edge of the field.) Overall [Darvish et al. \(2015\)](#) concludes that WVT is a robust density estimator.

The WVT algorithm and a comparison between several density estimation methods can be found in Sections 4.3 and 6 of [Darvish et al. \(2015\)](#) respectively.

★

### 3.3 Galaxy Zoo Hubble Morphological classifications

Morphological classifications of galaxies were obtained from the Galaxy Zoo Hubble<sup>1</sup> (GZH) citizen science project (Willett et al. 2017). GZH allowed several independent visual classifications of each galaxy image by volunteers, the question flowchart for each image is shown in Figure 4 of Willett et al. (2017). The GZH project provides detailed classifications of 119,849 galaxies from publicly-released *Hubble Space Telescope Legacy* programs conducted with the Advanced Camera for Surveys. In this study we used a subset of the total GZH sample corresponding to 84,954 galaxies found in the COSMOS Survey (Scoville et al. 2007; Koekemoer et al. 2007).

## 4 METHODS

### 4.1 Modelling Star Formation History

We used the publically available, Markov Chain Monte Carlo based (Foreman-Mackey et al. 2013), STARPY<sup>2</sup> code to infer the star formation history (SFH) of each galaxy in our sample. Inputs of redshift and of rest-frame U - V and V - J colours, combined with the stellar population model of Bruzual & Charlot (2003), a solar metallicity, and a Chabrier IMF Chabrier (2003) produces a SFH for each galaxy. These models do not account for intrinsic dust. An explanation of how STARPY works can be found in Section 3

The SFH model used is parameterised by  $t_q$  and  $\tau$  [Gyrs], where  $t_q$  is the onset time of quenching and  $\tau$  characterises the rate of quenching. Increasing  $\tau$  represents an exponentially slower quench. Assuming that all galaxies formed at  $t = 0$  [Gyrs] with an initial burst of constant SFR ( $\text{SFR}_0$ ), we write the SFH over cosmic time ( $0 \leq t$  [Gyrs]  $\leq 13.8$ ) as:

$$\text{SFR}(t) = \begin{cases} \text{SFR}_0(t_q) & t \leq t_q \\ \text{SFR}_0(t_q) \exp\left[-\frac{(t-t_q)}{\tau}\right] & t > t_q \end{cases} \quad (1)$$

$$P(\theta_k) = \begin{cases} 1 & 0 \leq t_q \text{ [Gyr]} \leq 13.8 \text{ and } 0 \leq \tau \text{ [Gyr]} \leq 4 \\ 0 & \text{otherwise} \end{cases} \quad (2)$$

## 5 CONCLUSIONS
